

The gray fields in the square indicate an acceleration of the existing trend. The trend there is accelerated because there are few things to stop it: Neither expressive long signals nor effective short signals.

The gray fields are vacuum in the final analysis where a trend can accelerate very quickly once it is given a push from below or above before it is stopped or caught by the signals which are lying at the diagonals. By those "buffers" the trend is blocked, then it reaches frequently the horizontal support or resistance lines where the price has to decide whether break or take a break or rebound.

Chart adjustments and time frames

You should always apply the GUNNER24 Forecasting Technique to candlestick charts and linear charts since others like the bar chart, the P&F chart as well as the logarithmic and the proportional chart descriptions would distort both the time unit and the price unit and they do not represent the reality one by one.

Using the GUNNER24 Forecasting Charting Software you should work with the following candlestick adjustment. And you should not often increase the distance between the candles to 2 or 3 pixels, for instance if perhaps you are not content with the Setup since the time lines do not check exactly or the price data does not follow the double arcs precisely.

In your charting software, you should pay attention to the possibility that by scrolling and moving your charts might scale automatically. Always work with a fixed price range in the chart.
